## DRP Library User's Manual

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

## Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
  2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other claims involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawings, charts, programs, algorithms, and application examples.
  3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
  4. You shall not alter, modify, copy, or reverse engineer any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copying or reverse engineering.
  5. Renesas Electronics products are classified according to the following two quality grades: “Standard” and “High Quality”. The intended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below.  
“Standard”: Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; industrial robots; etc.  
“High Quality”: Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.  
Unless expressly designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not intended or authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems; surgical implantations; etc.), or may cause serious property damage (space system; undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or any third parties arising from the use of any Renesas Electronics product that is inconsistent with any Renesas Electronics data sheet, user’s manual or other Renesas Electronics document.
  6. When using Renesas Electronics products, refer to the latest product information (data sheets, user’s manuals, application notes, “General Notes for Handling and Using Semiconductor Devices” in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat dissipation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions, failure or accident arising out of the use of Renesas Electronics products outside of such specified ranges.
  7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics, such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Unless designated as a high reliability product or a product for harsh environments in a Renesas Electronics data sheet or other Renesas Electronics document, Renesas Electronics products are not subject to radiation resistance design. You are responsible for implementing safety measures to guard against the possibility of bodily injury, injury or damage caused by fire, and/or danger to the public in the event of a failure or malfunction of Renesas Electronics products, such as safety design for hardware and software, including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult and impractical, you are responsible for evaluating the safety of the final products or systems manufactured by you.
  8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. You are responsible for carefully and sufficiently investigating applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive, and using Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
  9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall comply with any applicable export control laws and regulations promulgated and administered by the governments of any countries asserting jurisdiction over the parties or transactions.
  10. It is the responsibility of the buyer or distributor of Renesas Electronics products, or any other party who distributes, disposes of, or otherwise sells or transfers the product to a third party, to notify such third party in advance of the contents and conditions set forth in this document.
  11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
  12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.
- (Note 1) “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its directly or indirectly controlled subsidiaries.
- (Note 2) “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.

## General Precautions in the Handling of Microprocessing Unit and Microcontroller Unit Products

The following usage notes are applicable to all Microprocessing unit and Microcontroller unit products from Renesas. For detailed usage notes on the products covered by this document, refer to the relevant sections of the document as well as any technical updates that have been issued for the products.

### 1. Handling of Unused Pins

Handle unused pins in accordance with the directions given under Handling of Unused Pins in the manual.

- The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

### 2. Processing at Power-on

The state of the product is undefined at the moment when power is supplied.

- The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.  
In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed. In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

### 3. Prohibition of Access to Reserved Addresses

Access to reserved addresses is prohibited.

- The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

### 4. Clock Signals

After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

- When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

### 5. Differences between Products

Before changing from one product to another, i.e. to a product with a different part number, confirm that the change will not lead to problems.

- The characteristics of Microprocessing unit or Microcontroller unit products in the same group but having a different part number may differ in terms of the internal memory capacity, layout pattern, and other factors, which can affect the ranges of electrical characteristics, such as characteristic values, operating margins, immunity to noise, and amount of radiated noise. When changing to a product with a different part number, implement a system-evaluation test for the given product.

# How to Use This Manual

## 1. Purpose and Target Readers

This manual is intended to provide the user with an understanding of the functions of the DRP library and how to utilize them. It is aimed at users designing application systems making use of the DRP library. In order to use this manual, you will need a basic knowledge of programming languages and microprocessors.

Particular attention should be paid to the precautionary notes when using the manual. These notes occur within the body of the text, at the end of each section.

The revision history summarizes the locations of revisions and additions. It does not list all revisions. Refer to the text of the manual for details.

# 1. Introduction

## 1.1 Summary

This manual describes the functions and usage of the DRP library, which run on the dynamically reconfigurable processor (DRP) of RZ/A2M Group Microprocessors.

The DRP can perform various functions according to user's setting. In this document, the function performed by DRP is called "circuit", and the data representing circuit information is called "configuration data". Writing of the circuit to DRP can be performed by loading the configuration data using DRP Driver<sup>\*1</sup>. DRP Library is a collection of configuration data with various functions, mainly image processing.

Note 1. For details of DRP Driver, refer to "RZ/A2M Group DRP Driver User's Manual (R01US0355)".

## 1.2 Functions

The functions of the configuration data contained in the DRP library are listed below.

**Table 1.1 DRP Library Functions**

| Category          | Function Name           | Outline  | Page |
|-------------------|-------------------------|--|------|
| Simple ISP        | SimpleIsp               | ISP pipeline processing  | 11   |
| Image filter      | BinarizationFixed       | Converts the image to a binary image with a fixed threshold (fixed threshold)  | 18   |
|                   | BinarizationAdaptive    | Converts the image to a binary image with a dynamic threshold matching the surrounding image (adaptive threshold)              | 19   |
|                   | BinarizationAdaptiveBit | Converts the image to a binary image with a dynamic threshold matching the surrounding image (adaptive threshold) (bit output) | 23   |
|                   | Dilate                  | Dilation of white part in the image  | 25   |
|                   | Erode                   | Erosion of white part in the image   | 27   |
|                   | GammaCorrection         | Corrects the image with gamma value  | 29   |
|                   | GaussianBlur            | The image smoothing  | 31   |
|                   | MedianBlur              | Reduces the noise contained in the image   | 33   |
|                   | Sobel                   | Creates the edge of the image using Sobel filter   | 35   |
|                   | Prewitt                 | Creates the edge of the image using Prewitt filter   | 37   |
|                   | UnsharpMasking          | The image sharpening   | 39   |
|                   | Opening <sup>*1</sup>   | Noise reduction (Dilation after erosion)   | 41   |
|                   | Closing <sup>*1</sup>   | Noise reduction (Erosion after dilation)   | 44   |
| Image conversion  | Argb2Grayscale          | Converts from RGB to grayscale   | 47   |
|                   | Bayer2Grayscale         | Converts from RAW data acquired from CMOS to grayscale   | 48   |
|                   | Cropping                | Crops a part of the image  | 51   |
|                   | ResizeBilinearFixed     | Resizes the image (Using bilinear interpolation, Scale factor: 2 <sup>n</sup> )  | 53   |
|                   | ResizeBilinear          | Resizes the image (Using bilinear interpolation, Scale factor: any)  | 55   |
|                   | ResizeNearest           | Resizes the image (Using nearest interpolation, Scale factor: any)   | 57   |
| Feature detection | CannyCalculate          | Detects the edge of the image using the Canny method (performed by continuous processing of 2 functions)                       | 59   |
|                   | CannyHysteresis         |  | 61   |
|                   | CornerHarris            | Detects the corner contained in the image using the method devised by Chris Harris   | 63   |
|                   | CircleFitting           | Detects circle from the input image  | 65   |
| Other             | ReedSolomon             | Error correction using Reed-Solomon code   | 69   |
|                   | Histogram               | Generates a histogram from the input image   | 71   |

Note 1. This function can be executed by a combination of Dilate and Erode.

## 2. Operation Conditions

The DRP library operates under the conditions listed below.

**Table 2.1 Operation Conditions**

| Item           | Description  |
|----------------|--|
| Microprocessor | RZ/A2M Group Microprocessors* <sup>1</sup> <ul style="list-style-type: none"><li>• R7S921051VCBG</li><li>• R7S921052VCBG</li><li>• R7S921053VCBG</li></ul> |

Note 1. The DRP library operates on RZ/A2M Group Microprocessors equipped with a DRP function module. It will not operate on RZ/A2M Group Microprocessors without a DRP function module.

This library was confirmed to operate in the following development environment:

Renesas e<sup>2</sup> studio 7.3.0

The following toolchain is compatible:

GCC ARM Embedded Toolchain 6-2017-q2-update

### 3. File Structure

Figure 3.1 and Figure 3.1 shows the file structure of configuration data and header files in the DRP library.

|                                     |                         |
|-------------------------------------|-------------------------|

## 4. DRP Library Reference

### 4.1 How to Read the DRP Library Reference

In this section the specifications of the configuration data contained in the DRP library are presented in the format shown below.

#### Function name\*<sup>1</sup>

Function outline

|                                |   |
|--------------------------------|---|
| Configuration data file        | The name of the configuration data file. Use the DRP Driver's R_DK2_Load() function to load the data in the DRP.  |
| Supported version              | Lists the version of the configuration data that operates under present specification. Use the DRP Driver's R_DK2_GetInfo() function to get the version.  |
| Configuration data size (byte) | Lists the size of the configuration data. Lists all versions, if there are different versions.  |
| Header file                    | The name of the header file for using the configuration data. Use #include "header file" to include the file.   |
| Parameter                      | Lists the parameters required by the circuit. Parameters are passed from the CPU to the DRP by means of the DRP driver's R_DK2_Start() function. Parameters are defined as a structure within the header file. Before running the circuit, set the parameters on the CPU side. The data type defined in stdint.h is used.   |
| I/O details                    | Lists the details of the data specified by the parameters. Unless otherwise indicated, the same address may be specified for the input buffer address and output buffer address.  |
| Number of tiles                | The number of tiles used by the circuit. The DRP has 6 tiles. The DRP Driver's R_DK2_Load() function is used to assign circuits to tiles.   |
| Segmented processing           | Indicates that the function can be processed in parallel by multiple circuits. In parallel processing, the input image is divided up in the vertical direction and processed accordingly.<br>The segmented processing can be executed by utilizing the 6 tiles of DRP and loading multiple configuration data of 3 tiles or less. For details on loading multiple configuration data of 3 tiles or less into DRP, see the explanation of R_DK2_Load () function in "RZ/A2M Group DRP Driver User's Manual". |

Example: A case where the input image is divided into three portions in the vertical direction

|             |   |
|-------------|---|
| Description | Describes the specifications of the configuration data. |
| Note        | Additional notes appear here.                           |

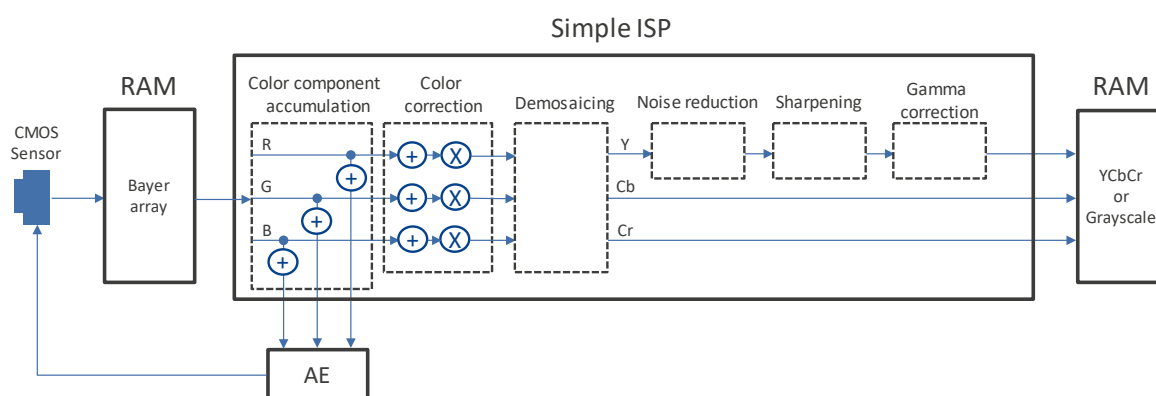

Note 1. The function name of configuration data is a character string that can be obtained from the configuration data by using the DRP Driver's R\_DK2\_GetInfo() function.

For information on using the API functions of the DRP Driver, refer to "RZ/A2M Group DRP Driver User's Manual (R01US0355)".

## 4.2 Simple ISP

### 4.2.1 Simple ISP overview

Simple ISP is an ISP (Image Signal Processor) most suitable for image recognition, and it performs color component accumulation, color correction, demosaicing, noise reduction, sharpening, and gamma correction on captured data (Bayer array). These functions are performed with pipeline processing and then output. This DRP library has been prepared for each output format, and there are two types, YCbCr output and Grayscale output. AE (automatic exposure control) can be realized by adjusting the gain of the CMOS sensor and the shutter speed on the CPU side by using the color component integrated value obtained from Simple ISP.

**Figure 4.1 Block Diagram of Simple ISP**

|                              |   |
|------------------------------|---|
| Color component accumulation | : Accumulated value for each RGB component of Bayer array                         |
| Color correction             | : Correction by addition and multiplication for each RGB component of Bayer array |
| Demosaicing                  | : Interpolation (ACPI / LI) from Bayer array to YCbCr or Y component              |
| Noise reduction              | : Noise reduction for Y component (Median filter)                                 |
| Sharpening                   | : Sharpening for Y component (Unsharp masking)                                    |
| Gamma correction             | : Gamma correction for Y component  |

#### 4.2.2 Simple ISP Library structure

The Simple ISP library has configuration data for two types of output format as shown in the table below. Each configuration data file has a 6-tile version optimized for performance and a 3-tile version to suppress the number of tiles, which can be used according to the application.

**Table 4.1 Simple ISP Library List**

| Output format | Tile numbers | Configuration data file name           |
|---------------|--------------|--|
| YCbCr         | 6 tiles      | r_drp_simple_isp_bayer2yuv_6.dat       |
|               | 3 tiles      | r_drp_simple_isp_bayer2yuv_3.dat       |
| Grayscale     | 6 tiles      | r_drp_simple_isp_bayer2grayscale_6.dat |
|               | 3 tiles      | r_drp_simple_isp_bayer2grayscale_3.dat |

## 4.2.3 Simple Isp API

| Segmented processing | Non-supported          |          |  |

## Description

## Input image

Bayer array of the input image is shown below. The data length of 1 pixel should be 8 bits.

## Output image

It is output with the image size specified by user settings for YCbCr422 (16 BPP) or Grayscale (8 BPP), parameter "width", "height".

## Each pipeline processing details

## Color Component Accumulation

It outputs the integrated result for each RGB component of Bayer array. For each of the three areas specified by the parameters area 1 to area 3, it accumulates each of the three components R, G, and B.

A total of nine accumulated values are output to the address specified by the "accumulate" parameter. 1 accumulated value = 32 bit length, please secure a total area of 36 bytes.

From the color component accumulated value, the average luminance can be calculated by the following formula.

$$\text{Average luminance} = \frac{0.299 \times \text{accumulation of R} + 0.587 \times \text{accumulation of G} + 0.114 \times \text{accumulation of B}}{\text{area width} \times \text{area height}}$$

In addition, the average of color components can be calculated by the following formula.

$$\text{Average of color component (R or B)} = \frac{\text{accumulation of R or B}}{\text{area width} \times \text{area height} \div 4}$$

$$\text{Average of color component (G)} = \frac{\text{accumulation of G}}{\text{area width} \times \text{area height} \div 2}$$

### Color Correction

For each of the RGB components of the Bayer array, the values set by parameters "bias\_r", "bias\_g", "bias\_b" are added, and the result is then multiplied by the value set by "gain\_r", "gain\_g", "gain\_b".

### Demosaicing

For YCbCr output, converts from Bayer array to YCbCr422 by Adaptive Color Plane Interpolation method (ACPI). For Grayscale output, it converts from Bayer array to Grayscale by Linear Interpolation method (LI).

### Noise Reduction

Noise reduction is performed by the Median filter algorithm.

You can adjust the amount of noise reduction by combining the input image and the Median filter noise reduction image at the blend ratio designated by the parameter "blend". When 0 is specified for "blend", noise reduction is turned off.

$$\text{Output} = \frac{\text{Input image} \times (256 - \text{blend}) + \text{median image} \times \text{blend}}{256}$$

### Sharpening

Sharpens the image using the Unsharp masking algorithm. For input, sharpening is performed by subtracting the edge created by the following 8-direction Laplacian filter. Strength of sharpening is specified as "strength", and threshold of amplitude difference without sharpening is designated by "coring".

8-direction Laplacian filter

|   |    |   |
|---|----|---|
| 1 | 1  | 1 |
| 1 | -8 | 1 |
| 1 | 1  | 1 |

Sharpening processing calculation is as follows.

$$\text{Output} = \text{Input} - \left( \frac{\text{strength}}{256} \times A \right)$$

A: result of applying 8-direction Laplacian filter

We compare by "coring" so as not to execute sharpening processing on a weak edge with a low amplitude difference. It does not filter on the pixel of interest that satisfies the following formula.

$$\text{coring} \geq |A|$$

### Gamma Correction

Please store the gamma table at the address specified by parameter "table".

It converts the pixel value by referring to the LUT, which is "table" with values from 0 to 255.

### Example

#### Exposure Control Example

You can calculate the average luminance from the result of color component integration, and perform exposure control using this average luminance. If the average luminance is low, you can adjust this value by decreasing the shutter speed, increasing the gain, increasing the average luminance, increasing the shutter speed, or lowering the gain.

#### White Balance Example

Using the result of color component accumulation, you can adjust the white balance by performing gain correction as follows.

Based on the G component as a main component, compare the accumulation results of R and B color components and calculate the set value of gain from that ratio.

Example:

In the case of the above example, G is 1.42 times larger than R and G is 1.25 larger than times from B, so set R gain to 1.42 times and B gain to 1.25 times.

Note

None

## 4.3 Image Filter

### 4.3.1 BinarizationFixed

#### BinarizationFixed

Converts the image to a binary image with a fixed threshold (fixed threshold)

|                                |  |                  |   |
|--------------------------------|--|------------------|---|
| Configuration data file        | r_drp_binarization_fixed.dat   |                  |   |
| Supported version              | 0.90   |                  |   |
| Configuration data size (byte) | 16960(Ver.0.90)  |                  |   |
| Header file                    | r_drp_binarization_fixed.h   |                  |   |
| Parameter                      | Structure name   |                  |   |
|                                | r_drp_binarization_fixed_t   |                  |   |
|                                | Member name  | Type             | Description   |
|                                | src  | uint32_t         | Input image address                                     |
|                                | dst  | uint32_t         | Output image address                                    |
|                                | width  | uint16_t         | Image width (pixels)                                    |
|                                | height   | uint16_t         | Image height (pixels)                                   |
|                                | threshold  | uint8_t          | Binarization threshold (0 to 255)                       |
| I/O details                    | Input image  | Address:         | Specified by src.                                       |
|                                |  | Width (pixels):  | Specified by width. (32 to 1280, integer multiple of 8) |
|                                |  | Height (pixels): | Specified by height. (1 to 960)                         |
|                                |  | Format:          | 8-bit grayscale (1 byte per pixel)                      |
|                                |  | Data size:       | (width) × (height) × 1 byte                             |
|                                | Output image   | Address:         | Specified by dst.                                       |

|                                |                                 | Height (pixels): | Same as input image   |
|                                |                                 | Format:          | 8-bit grayscale (0 or 255) (1 byte per pixel)   |
|                                |                                 | Data size:       | (width) × (height) × 1 byte   |
|                                | Work area                       | Address:         | Specified by work.  |
|                                |                                 | Data size:       | $((\text{width} \times \text{height}) \div 64) + 2$ bytes   |
|                                |                                 | Description      | The area used to store average brightness values. Refer to the explanation below for more on average brightness values. |
| Number of tiles                | 3                               |                  |   |
| Segmented processing           | Not supported                   |                  |   |

**Description** This function binarizes the image at the address specified by src and outputs the result to the address specified by dst.

In the first part of binarization processing, the function divides the input image into blocks of  $8 \times 8$  pixels and calculates the average brightness of each. Then it calculates thresholds from the average brightness values and binarizes the input image.

The method of calculating the average brightness value is as follows. First, blocks of  $8 \times 8$  pixels are delimited, starting from the upper left corner of the input image. Then the maximum and minimum brightness values are sought for each block and the brightness differential is obtained. For blocks where the brightness differential exceeds the range value, the average of the brightness values within the block is used as the average brightness value. For blocks where the brightness differential is equal to or less than the range value, the average brightness value is obtained from the average brightness values of 3 adjacent blocks (above left, above, and left). The method of obtaining the average brightness value is shown in detail below.

- (1) Block where the brightness differential exceeds the value of range

Average brightness value = total brightness values of  $8 \times 8$  pixels  $\div$  64

- (2) Block where the brightness differential is equal to or less than the value of range

Average brightness value

$$= (\text{average brightness value of A} \\ + \text{average brightness value of B} \\ + (\text{average brightness value of C} \times 2)) \div 4$$

However, if the block (D) whose average brightness value we wish to calculate is on the top or left edge of the input image, a value equal to 1/2 the minimum brightness value of D is used because it is not possible to secure average brightness values for the 3 adjacent blocks.

To calculate the thresholds from the average brightness values, groups of  $5 \times 5$  blocks are delimited, each with the block containing the pixels to be binarized (the “target pixels”) at the center. The threshold is then calculated from the average brightness values of the group of  $5 \times 5$  blocks. The following equation is used to obtain the threshold.

$$\text{Threshold} = \{(0,0) \text{ average brightness value} \\ + (1,0) \text{ average brightness value} + \dots + (4,4) \text{ average brightness value}\} \\ \div 25$$

|       |       |       |       |       |
|-------|-------|-------|-------|-------|
| (0,0) | (1,0) | (2,0) | (3,0) | (4,0) |
| (0,1) | (1,1) | (2,1) | (3,1) | (4,1) |
| (0,2) | (1,2) | (2,2) | (3,2) | (4,2) |
| (0,3) | (1,3) | (2,3) | (3,3) | (4,3) |
| (0,4) | (1,4) | (2,4) | (3,4) | (4,4) |

Block of 8 × 8 pixels

However, if the block containing the target pixels is at the edge of the input image, making it impossible to secure a group of 5 × 5 blocks, the threshold is calculated as described below.

- If the block is within 2 blocks of the top edge  
The block is moved to the center to secure a group of 5 × 5 blocks, and the threshold is calculated.

- If the block is within 2 blocks of the left edge  
0 is used as the threshold.
- If the block is within 2 blocks of the right edge  
The threshold of the block immediately to the left is used.
- If the block is within 2 blocks of the bottom edge  
The threshold of the block immediately above is used.

Note that the results of binarization change as shown below, according to the value specified for range.

---

Using a smaller value for range makes it possible to minimize white blowout and blocked up shadows in the binarized image, but the effects of noise will be more noticeable. Using a larger value for range will reduce the effects of noise but result in more white blowout and blocked up shadows. It is important to set range to a value appropriate for the characteristics of the input image (which are influenced by factors such as the performance of the connected camera and ambient light conditions).

This function allows the same address to be specified for both src and dst.

|                                |                                     | Height (pixels): | Same as input image   |
|                                |                                     | Format:          | 1 bit per pixel (Refer to the description for details.)   |
|                                |                                     | Data size:       | (width) × (height) ÷ 8 bytes  |
|                                | Work area                           | Address:         | Specified by work.  |
|                                |                                     | Data size:       | ((width × height) ÷ 64) + 2 bytes   |
|                                |                                     | Description      | The area used to store average brightness values. Refer to the explanation below for more on average brightness values. |
| Number of tiles                | 3                                   |                  |   |
| Segmented processing           | Not supported                       |                  |   |

**Description** This function performs the same processing as that described in 4.2.2, BinarizationAdaptive. It differs from the function described in 4.2.2, BinarizationAdaptive, only in the output format for processing results.

The output format of this function uses 1 bit to represent 1 pixel. The arrangement of the bits in the image starts with bit 0 at x coordinate 0, followed by bit 1 at x coordinate 1, and so on. In addition, white is 0 and black is 1.

Setting the range value for this function to 0x18 produces results equivalent to the binarization performed in ZXing ("Zebra Crossing") barcode scanning (implemented by the calculateBlackPoints function and calculateThresholdForBlock function).

Reference URL: <https://github.com/zxing/zxing>

This function allows the same address to be specified for both src and dst.

**Note** This function differs from the function described in 4.2.2, BinarizationAdaptive, only in the output format for processing results. But when BinarizationAdaptive is a pixel outputting 0, BinarizationAdaptiveBit outputs 1, and when BinarizationAdaptive is a pixel outputting 255, BinarizationAdaptiveBit is 0 is output. Note this reverse relationship.

## 4.3.4 Dilate

## Dilate

Dilation of white part in the image

|                                |                  |                  |   |

| Number of tiles                | 1                |                  |   |
| Segmented processing           | Supported        |                  |   |

**Description** This function expands the bright portions of the image at the address specified by src and outputs the result to the address specified by dst.

The maximum value of the 3 × 3 block with the target pixel at the center is set as the new value of the target pixel. When a black and white binary image is input, the white portions appear to expand outward around the pixel. The processing performed is similar to that of the OpenCV `cv::dilate()` function when border processing is set to `BORDER_REPLICATE`.

Reference URL: <https://opencv.org/>

A processing example using a binarized image as the input image is shown below.

Input image

Output image

This function allows specification of the same address for both src and dst as long as the processing is not segmented.

**Note** None

## 4.3.5 Erode

## Erode

Erosion of white part in the image

|                                |                            | Format:          | 8-bit grayscale (1 byte per pixel)                      |
|                                |                            | Data size:       | (width) × (height) × 1 byte                             |
| Number of tiles                | 1                          |                  |   |
| Segmented processing           | Supported                  |                  |   |

**Description** This function applies Gamma correction to the image at the address specified by src and outputs the result to the address specified by dst.

The function performs Gamma correction by obtaining post-correction brightness values from a lookup table based on a Gamma correction ( $\gamma$ ) of 2.0. Post-correction brightness values are calculated using the equation below, where the Gamma correction value is represented as  $\gamma$ , the pre-correction brightness value as src, and the post-correction brightness value as dst.

$$\text{dst} = \left( \frac{\text{src}}{255} \right)^{\frac{1}{\gamma}} \times 255$$

For the calculation results using the above equation when  $\gamma = 2.0$ , the value of dst is rounded off after the decimal point. Some examples of src values and their corresponding dst output values are shown below.

|     |   |    |    |    |     |     |     |     |
|-----|---|----|----|----|-----|-----|-----|-----|
| src | 0 | 1  | 2  | 3  | ... | 253 | 254 | 255 |
| dst | 0 | 16 | 23 | 28 | ... | 254 | 254 | 255 |

This function allows the same address to be specified for both src and dst.

| Segmented processing           | Supported       |                  |   |

**Description** This function uses a Sobel filter to emphasize the edges in the image at the address specified by src and outputs the result to the address specified by dst.

The function performs the calculations shown below on a 1 pixel band around the target pixel (an area of  $3 \times 3$  pixels) in order to emphasize edges in the horizontal and vertical directions.

This function allows specification of the same address for both src and dst as long as the processing is not segmented.

**Note** None

## 4.3.10 Prewitt

## Prewitt

Creates the edge of the image using Prewitt filter

|                                |                   |                  |   |

|                                | bottom                    | uint8_t          | 1: Bottom edge border processing<br>0: No bottom edge border processing<br>Specify 1 if the input image is not segmented.<br>For segmenting the input image for processing, specify 1 if the input image reaches the bottom edge of the source image, otherwise, specify 0. |
| I/O details                    | Input image               | Address:         | Specified by src.   |
|                                |                           | Width (pixels):  | Specified by width. (16 to 1280)  |
|                                |                           | Height (pixels): | Specified by height. (8 to 960)   |
|                                |                           | Format:          | 8-bit grayscale (1 byte per pixel)  |
|                                |                           | Data size:       | (width) × (height) × 1 byte   |
|                                | Output image              | Address:         | Specified by dst.   |
|                                |                           | Width (pixels):  | Same as input image   |
|                                |                           | Height (pixels): | Same as input image   |
|                                |                           | Format:          | 8-bit grayscale (1 byte per pixel)  |
|                                |                           | Data size:       | (width) × (height) × 1 byte   |
| Number of tiles                | 2                         |                  |   |
| Segmented processing           | Supported                 |                  |   |

---

**Description** This function sharpens (enhances the edges in) the image at the address specified by src and outputs the result to the address specified by dst.

The amount of emphasis can be adjusted using the strength parameter. A larger strength value corresponds to more emphasis of the edges in the image.

For UnsharpMasking, the coefficients below used by the OpenCV `cv::filter2D()` function are typical. (k is the coefficient representing sharpening strength. A value of 0 means no sharpening.)

|        |                 |        |
|--------|-----------------|--------|
| $-k/9$ | $-k/9$          | $-k/9$ |
| $-k/9$ | $1 + (8 * k/9)$ | $-k/9$ |
| $-k/9$ | $-k/9$          | $-k/9$ |

Reference URL: <https://opencv.org/>

This function uses the coefficients below, which approximate the above coefficients using a fixed decimal. k' is specified as strength.

|           |                           |           |
|-----------|---------------------------|-----------|
| $-k'/256$ | $-k'/256$                 | $-k'/256$ |
| $-k'/256$ | $(9 * 28 + (8 * k'))/256$ | $-k'/256$ |
| $-k'/256$ | $-k'/256$                 | $-k'/256$ |

By specifying a value 28 times the k value as strength, UnsharpMasking can be performed. For example, if a value of 28 is specified for strength, the result would be equivalent to performing UnsharpMasking when  $k = 1.0$ .

This function allows specification of the same address for both src and dst as long as the processing is not segmented.

### 4.3.12 Opening

## Opening

Noise reduction (Dilation after erosion)

**Description** Opening involves the repeated application of shrinkage (erosion) within the white parts, followed by the repeated application of expansion (dilation). The erosion and dilation are repeated the same number of times. This is useful for eliminating noise in monochrome images.

In other words, this processing involves the application of a combination of the Erode and Dilate functions of the DRP Library. Refer to the respective sections for the specifications of the Erode function and the Dilate function.

The explanation of the Opening processing is for when the number of iterations of both the Erode and Dilate functions is three.

### Erosion

An overview of repeating Erode processing three times is shown below.

In the first iteration of Erode processing, the image which is input is set as the input image for processing by the Erode function.

In the second iteration of Erode processing, the output image of the first iteration is set as the input image for processing by the Erode function.

In the third iteration of Erode processing, the output image of the second iteration is set as the input image for processing by the Erode function.

### Dilation

An overview of repeating Dilate processing three times is shown below.

In the first iteration of Dilate processing, the output image of the third Erode processing is set as the input image for processing by the Dilate function.

In the second iteration of Dilate processing, the output image of the first iteration is set as the input image for processing by the Dilate function.

In the third iteration of Dilate processing, the output image of the second iteration is set as the input image for processing by the Dilate function.

The output image of the third Dilate processing becomes the result image of performing Opening.

The processing performed by this function is equivalent to that of the OpenCV `cv::morphologyEx` function with specifying `MORPH_OPEN` to the argument `op`, `cv::Mat()` to kernel, `Point(-1,-1)` to anchor, the iteration number to `iterations`, and `BORDER_REPLICATE` to `borderType`.

Reference URL: <https://opencv.org/>

#### Note

If the processing of Erode and Dilate is to be segmented, only proceed with a next stage of processing after all segments of the resulting images in the current stage have been obtained.

### 4.3.13 Closing

## Closing

Noise reduction (Erosion after dilation)

**Description** Closing involves the repeated application of expansion (dilation) within the white parts, followed by the repeated application of shrinkage (erosion). The dilation and erosion are repeated the same number of times. This is useful for eliminating noise in monochrome images.

In other words, this processing involves the application of a combination of the Dilate and Erode functions of the DRP Library. Refer to the respective sections for the specifications of the Dilate function and the Erode function.

The explanation of the Closing processing is for when the number of iterations of both the Dilate and Erode functions is three.

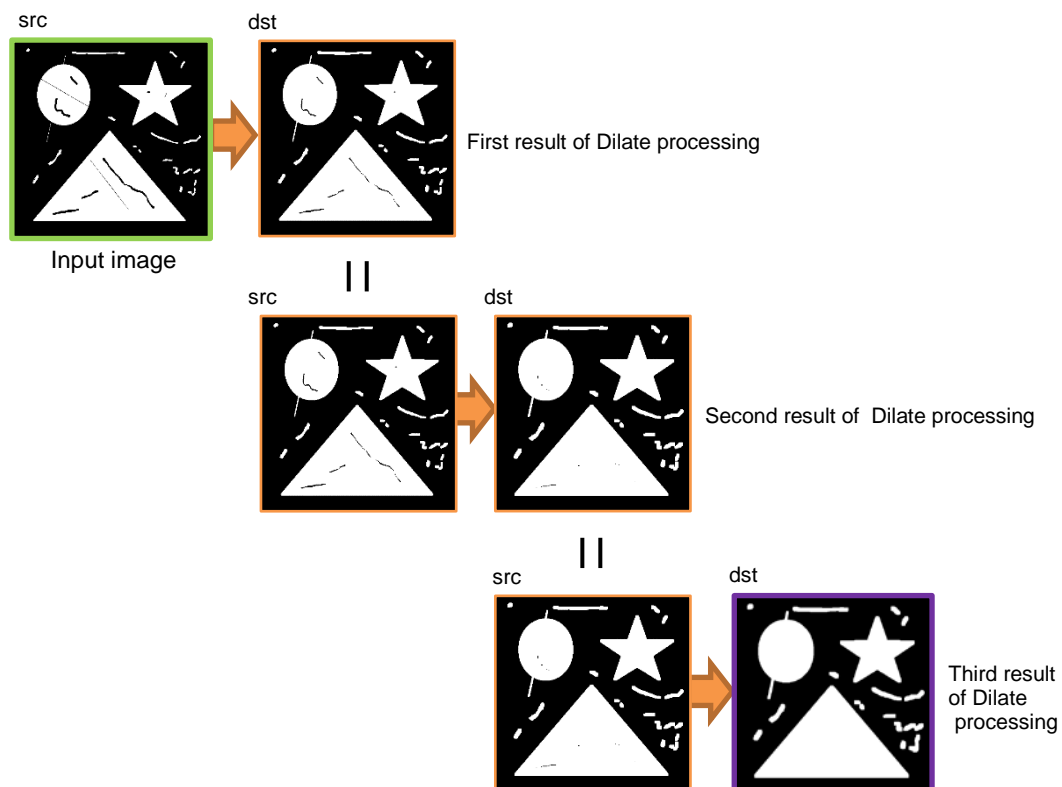

### Dilation

An overview of repeating Dilate processing three times is shown below.

In the first iteration of Dilate processing, the image which is input is set as the input image for processing by the Dilate function.

In the second iteration of Dilate processing, the output image of the first iteration is set as the input image for processing by the Dilate function.

In the third iteration of Dilate processing, the output image of the second iteration is set as the input image for processing by the Dilate function.

## Erosion

An overview of repeating Erode processing three times is shown below.

In the first iteration of Erode processing, the output image of the third Dilate processing is set as the input image for processing by the Erode function.

In the second iteration of Erode processing, the output image of the first iteration is set as the input image for processing by the Erode function.

In the third iteration of Erode processing, the output image of the second iteration is set as the input image for processing by the Erode function.

The output image of the third Erode processing becomes the result image of performing Closing.

The processing performed by this function is equivalent to that of the OpenCV `cv::morphologyEx` function with specifying `MORPH_CLOSE` to the argument `op`, `cv::Mat()` to kernel, `Point(-1,-1)` to anchor, the iteration number to iterations, and `BORDER_REPLICATE` to borderType.

Reference URL: <https://opencv.org/>

### Note

If the processing of Dilate and Erode is to be segmented, only proceed with a next stage of processing after all segments of the resulting images in the current stage have been obtained.

## 4.4 Image Conversion

### 4.4.1 Argb2Grayscale

#### Argb2Grayscale

Converts from RGB to grayscale

|                                | bottom                    | uint8_t  | 1: Bottom edge border processing<br>0: No bottom edge border processing<br>Specify 1 if the input image is not segmented.<br>For segmenting the input image for processing, specify 1 if the input image reaches the bottom edge of the source image, otherwise, specify 0. |

|  |              |                  |                                    |
|--|--------------|------------------|------------------------------------|
| I/O details  | Input image  | Address:         | Specified by src.                  |
|  |              | Width (pixels):  | Specified by width. (16 to 1280)   |
|  |              | Height (pixels): | Specified by height. (4 to 960)    |
|  |              | Data size:       | (width) × (height) × 1 byte        |
| Format   |              |                  |                                    |
| The input image format is as follows. When the coordinates of the upper left corner in input image are (0,0), both X and Y coordinates being even numbers represents “red,” both being odd numbers represents “blue,” and any other combination represents “green.” This produces the Bayer array shown below.   |              |                  |                                    |
| <div><div><div><div>(0,0)<br/>R</div><div>(1,0)<br/>G</div><div>(2,0)<br/>R</div><div>(3,0)<br/>G</div><div>(4,0)<br/>R</div><div>(5,0)<br/>G</div></div><div><div>(0,1)<br/>G</div><div>(1,1)<br/>B</div><div>(2,1)<br/>G</div><div>(3,1)<br/>B</div><div>(4,1)<br/>G</div><div>(5,1)<br/>B</div></div><div><div>(0,2)<br/>R</div><div>(1,2)<br/>G</div><div>(2,2)<br/>R</div><div>(3,2)<br/>G</div><div>(4,2)<br/>R</div><div>(5,2)<br/>G</div></div><div><div>(0,3)<br/>G</div><div>(1,3)<br/>B</div><div>(2,3)<br/>G</div><div>(3,3)<br/>B</div><div>(4,3)<br/>G</div><div>(5,3)<br/>B</div></div><div><div>(0,4)<br/>R</div><div>(1,4)<br/>G</div><div>(2,4)<br/>R</div><div>(3,4)<br/>G</div><div>(4,4)<br/>R</div><div>(5,4)<br/>G</div></div><div><div>(0,5)<br/>G</div><div>(1,5)<br/>B</div><div>(2,5)<br/>G</div><div>(3,5)<br/>B</div><div>(4,5)<br/>G</div><div>(5,5)<br/>B</div></div></div><div>(X coordinate, Y coordinate) =<br/>(even, even): red<br/>(even, odd): green<br/>(odd, even): green<br/>(odd, odd): blue</div></div> |              |                  |                                    |
| Bayer arrays other than the above can be supported either by changing the camera settings or using the VIN function of the RZ/A2M. Refer to the description below for details.   |              |                  |                                    |
|  | Output image | Address:         | Specified by dst.                  |
|  |              | Width (pixels):  | Same as input image                |
|  |              | Height (pixels): | Same as input image                |
|  |              | Format:          | 8-bit grayscale (1 byte per pixel) |
|  |              | Data size:       | (width) × (height) × 1 byte        |
| Number of tiles  | 1            |                  |                                    |
| Segmented processing   | Supported    |                  |                                    |

|             |   |
|-------------|---|
| Description | <p>This function converts the image at the address specified by src from Bayer format to 8-bit grayscale format and outputs the result to the address specified by dst.</p> |
|-------------|---|

First, the function converts the input image to RGB by linear interpolation using a  $3 \times 3$  filter. Then it converts from RGB to Y and calculates brightness values.

In linear interpolation using a  $3 \times 3$  filter, the  $3 \times 3$  grid consists of the pixel to be converted and the pixels adjacent to it. The pixel values are multiplied by the following multipliers and the results for each color component are added up.

Value of center pixel:  $4/16\times$

Values of pixels immediately above, below, left, and right:  $2/16\times$

Values of diagonally adjacent pixels:  $1/16\times$

These are then multiplied by the reciprocals of the Bayer color density values (4 for red and blue, 2 for green), to obtain the RGB values for the pixel being converted.

- Center:  $4/16\times$
- Above, below, left, and right:  $2/16\times$
- Diagonally adjacent:  $1/16\times$

Each is multiplied by the respective multiplier indicated above and the results for each color component added up. These are then multiplied by the reciprocals of the color density values (4 for red and blue, 2 for green).

The following equation is used to convert from RGB to Y.

$$Y = (\text{Red} * 76 + \text{Green} * 152 + \text{Blue} * 28) / 256$$

For the pixels at the left and right edges of the screen, a portion of the  $3 \times 3$  filter grid is outside the input image area and therefore cannot be referenced. Instead, border reflection (OpenCV BORDER\_REFLECT\_101), in which the values of pixels 1 line further inward are referenced, is performed.

Reference URL: <https://opencv.org/>

When top and bottom are both set to 1, equivalent border reflection is also performed at the top and bottom edges of the image. Set top and bottom to 1 if the input image is not segmented.

When using a camera with a Bayer array that differs from that shown in the figure for "Input image" under "I/O details," crop and capture the image in a position such that the upper left corner is red. To crop the image, either clip the output image range of the camera or, when using an MIPI camera, clip the input image range on the RZ/A2M. For information on settings for the latter method, refer to section 48, Video Input Module, in RZ/A2M Group User's Manual: Hardware, or the description of range clipping (pre-stage) in the user's manual of the MIPI driver.

This function allows specification of the same address for both src and dst as long as the processing is not segmented.

**Description** This function crops a rectangular portion of the size specified by the offsets from the image at the address specified by src and outputs it to the address specified by dst.

This function allows the same address to be specified for both src and dst.

**Note** The arguments should be set such that the cropped rectangular area does not extend outside of the input image area. If `offset_x + dst_width` exceeds `src_width`, or if `offset_y + dst_height` exceeds `src_height`, processing terminates with no cropping performed.

## 4.4.4 ResizeBilinearFixed

## ResizeBilinearFixed

Resizes the image (Using bilinear interpolation, Scale factor: 2<sup>n</sup>)

|                                |                                 |
|--------------------------------|---------------------------------|
| Configuration data file        | r_drp_resize_bilinear_fixed.dat |
| Supported version              | 0.91                            |

| Segmented processing           | Not supported             |                  |  |

**Description** This function enlarges or reduces the image at the address specified by src and outputs the result to the address specified by dst.

It is necessary to add or remove pixels when the image is enlarged or reduced, and this function uses bilinear method for this purpose.

In the bilinear method, a grid of  $2 \times 2$  pixels peripheral to the input image in the position corresponding to the target pixel of the output image is used and linear interpolation is applied. This function uses the following calculations for the bilinear method.

Assuming that the coordinate (sx,sy) in the input image corresponds to the coordinate (dx,dy) of the output image, sx and sy are expressed by the following equations.

$$sx = (dx + 0.5) \times \text{src\_width} \div \text{dst\_width} - 0.5$$

$$sy = (dy + 0.5) \times \text{src\_height} \div \text{dst\_height} - 0.5$$

Assuming that fsx=Floor(sx) and fsy=Floor(sy), the coordinates of the grid of  $2 \times 2$  pixels peripheral to (sx,sy) are (fsx,fsy), (fsx+1,fsy), (fsx,fsy+1) and (fsx+1,fsy+1).

Assuming that the brightness value at the coordinate (x,y) of the input image is src(x,y) and the brightness value at the coordinate (x,y) of the output image is dst(x,y), dst(dx,dy) is expressed by the following equation.

$$\begin{aligned} \text{dst}(dx, dy) = & (1 - b) \times (1 - a) \times \text{src}(fsx, fsy) + (1 - b) \times a \times \text{src}(fsx + 1, fsy) \\ & + b \times (1 - a) \times \text{src}(fsx, fsy + 1) + b \times a \times \text{src}(fsx + 1, fsy + 1) \end{aligned}$$

However,  $a = sx - fsx$ ,  $b = sy - fsy$

The processing performed by this function is equivalent to that of the OpenCV cv::resize function with specifying dst\_width to the argument dsize.width, dst\_height to dsize.height, and INTER\_LINEAR to interpolation.

|             |   |
|-------------|---|
| Description | This function enlarges or reduces the image at the address specified by src and outputs the result to the address specified by dst. |
|-------------|---|

Assuming that the brightness value at the coordinate (x,y) of the input image is  $\text{src}(x,y)$ , the brightness value  $\text{dst}(dx,dy)$  at the coordinate (dx,dy) of the output image is expressed by the following equation.

$$\text{dst}(dx,dy) = \text{src}(dx \times \text{src\_width} \div \text{dst\_width}, dy \times \text{src\_height} \div \text{dst\_height})$$

The coordinate values are truncated after the decimal point.

The following figure shows an example of the output image when the size of the input image is 250 x 100 and that of the output image is 100 x 200.

The processing performed by this function is equivalent to that of the OpenCV `cv::resize` function with specifying `dst_width` to the argument `dsize.width`, `dst_height` to `dsize.height`, and `INTER_NEAREST` to interpolation.

|                      |  |
|----------------------|--|
| Number of tiles      | 2  |
| Segmented processing | Supported  |
| Description          | This function uses the Canny method to find edge candidates in the image at the address specified by src and outputs the result to the address specified by dst. |

Canny edge detection produces few edge detection errors. It is also capable of outputting edges as thin lines. Canny edge detection consists of the following processing steps, performed in the order shown:

1. Noise is eliminated (Gaussian filter).
2. The edge strength and degree of accuracy is calculated, non-maximum values are suppressed, and the edges are classified.
3. Edges are determined by hysteresis threshold processing.

The OpenCV `cv::Canny()` function performs all of the above processing. This library produces similar edge output by using the `GaussianBlur` function for step 1, the `CannyCalculate` function for step 2, and the `CannyHysteresis` function for step 3.

Reference URL: <https://opencv.org/>

The edge candidates output by the function fall into 3 categories based on edge strength: non-edge, weak edge, and strong edge. The thresholds for determining weak edges and strong edges are set by the `threshold_low` and `threshold_high` parameters. The lower the thresholds, the larger the number of edge candidates.

Input image

Output image  
threshold\_low=0x18  
threshold\_high=0x30

Output image  
threshold\_low=0x05  
threshold\_high=0x28

Display characteristics used:

Gray: Weak edge

White: Strong edge

The function calculates the edge strength and direction as described below.

$$G_x = \begin{bmatrix} G_{00} & G_{01} & G_{02} \\ G_{10} & G_{11} & G_{12} \\ G_{20} & G_{21} & G_{22} \end{bmatrix} \times \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}$$

$$G_y = \begin{bmatrix} G_{00} & G_{01} & G_{02} \\ G_{10} & G_{11} & G_{12} \\ G_{20} & G_{21} & G_{22} \end{bmatrix} \times \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix}$$

$$\text{Edge strength} = ((G_x)^2 + (G_y)^2) >> 7$$

if ( 3 \* abs(Gx) <= 8 \* abs(Gy)) // 21 degrees or less

Edge direction = DIR0

else if (20 \* abs(Gx) > 8 \* abs(Gy)) // More than 67 degrees

Edge direction = DIR90

else

Edge direction = (sign(Gx)==sign(Gy)) ? DIR45 : DIR135

|                      |   |
|----------------------|---|
| Number of tiles      | 6   |
| Segmented processing | Not supported   |
| Description          | This function performs hysteresis threshold processing on the image (edge candidates) at the address specified by src and outputs the resulting edge image to the address specified by dst. (Edge detection using the Canny method is the second part of the processing. For details, refer to the description of the CannyCalculate function.) |

In hysteresis threshold processing the input edge candidates are checked, each weak edge that is connected to a strong edge is output as an edge, and each weak edge that is not connected to a strong edge is output as a non-edge.

Checking is performed to confirm connections both above and below. When a weak edge is determined to be an edge, any weak edge connected to that edge must also be checked, so the processing is repeated up to the maximum number of iterations. If search continue twice that do not change to strong edge continue, the process ends. (The processing time and accuracy should be considered when choosing the setting value.)

## Description

This function performs circle fitting processing of the image at the address specified by src, and outputs the coordinates of the center, the radius, and the score for the circle that was found to the range from the address specified by dst.

In the case of the image in which a single edge can be recognized, the image has different brightnesses at point A in the image and at another point B which is across the edge from point A.

An image having an edge of oblique line

Circle fitting processing starts with the assumptions that a circle is to be found by the search, of a circle P, a concentric circle Q having a larger radius, and a concentric circle R having a smaller radius. The absolute value of the difference in brightness between the regions of the outlines of circles Q and R is calculated by using the above concept.

Targets of calculation in circle fitting

The points at which the brightness values are sampled for the circle having the center coordinate (x,y) and radius r are the 48 points starting from the point (x+r,y) and distributed around the circumference of the circle at an angular interval of 7.5 degrees. If the values of the coordinates of a sampling point are not integers, the decimal fraction in the value is rounded up or down.

The score in circle fitting for a circle having center coordinate (x,y) and radius r is calculated in the way described below.

$$\text{score} = \frac{|(\text{Total of brightness values of 48 points on the circumference with the center coordinate (x,y) and radius (r + step)}) - (\text{Total of brightness values of 48 points on the circumference with the center coordinate (x,y) and radius (r - step)})|}{2}$$

The center coordinate and radius are varied to search for the values that deliver the highest score, and the x and y coordinates of the center, radius r, and score of the final result are output.

If scores for multiple coordinates and radii are equal highest, the order of priority listed below is applied to obtain the final result.

1. The smallest radius
2. The smallest y-coordinate value
3. The smallest x-coordinate value

The parameters c\_area\_startx, c\_area\_starty, c\_area\_width, and c\_area\_height determine the area to be searched for the center of a circle as shown in the figure below. Set the area to be searched for the center of a circle to be wholly within the area of the input image.

The circle fitting processing is performed from the center coordinates (c\_area\_startx + step \* n, c\_area\_starty + step \* n) [n is an integer not less than 0]. However, if part of a circle is outside the area of the input image, it is deemed not to be a circle.

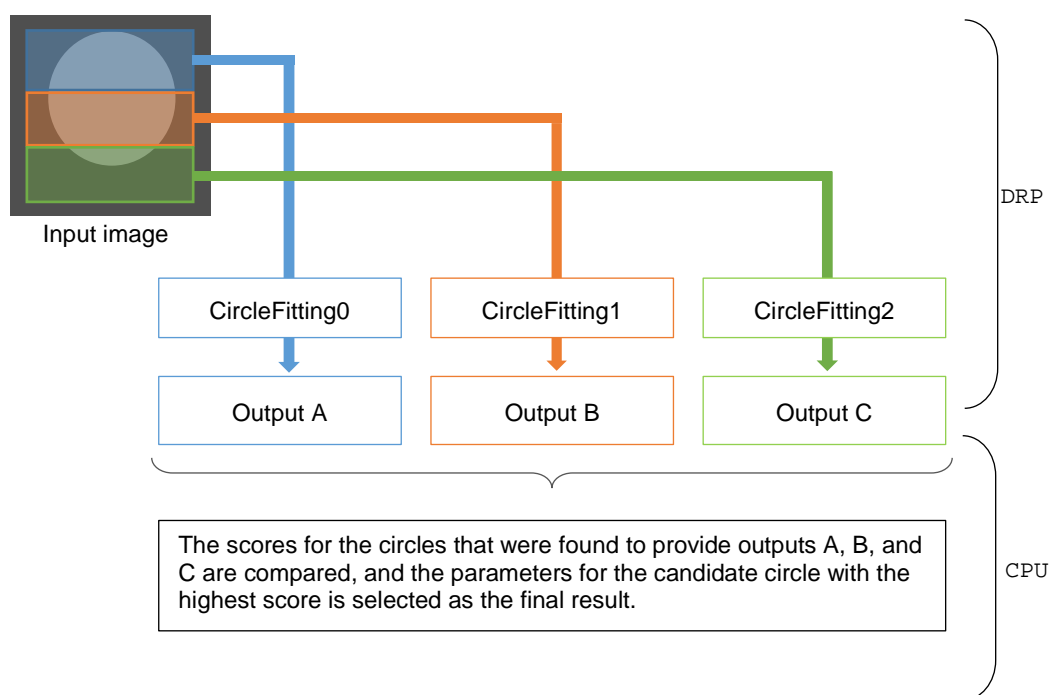

This function allows processing to be segmented with the aid of the CPU.

An example of segmentation for three parallel flows of processing is shown below.

The search area is segmented into the three areas `CircleFitting0`, `CircleFitting1`, and `CircleFitting2`, and the prescribed `dst`, `work`, `c_area_startx`, `c_area_starty`, `c_area_width`, and `c_area_height` are specified for the three respective areas to perform the circle fitting processing from the same center coordinates as those before the segmentation. Use the same settings of `src`, `src_width`, `src_height`, `min_radius`, `max_radius`, and `step`.

After the DRP completes the circle fitting processing, the scores (of the circles that were found) are output to the `dst` area from `CircleFitting0`, `CircleFitting1`, and `CircleFitting2`, and the highest score is selected as the final result. Segmented processing can thus be realized.

**Note** If the parameter settings are such that part or the whole of any candidate circle is out of the area of input image, regardless of the point in the search area that is set as the center, the values of all output variables will always be 0.

## 4.6 Other

### 4.6.1 ReedSolomon

## ReedSolomon

Error correction using Reed-Solomon code

**Description** This function calculates a histogram from the image data at the address specified by src and outputs the result to the address specified by dst. Specifying the data size (= width x height) of the image as data\_size enables the input of an image as follows.

The bin areas for this function are specified by using hist\_size and ranges.

Input data

Output data

To set the upper and lower limits for the hist\_size bins, specify the bin areas for the (hist\_size + 1) bins.

The lower limit for the i-th bin becomes  $\text{range} + i \times 2$ .

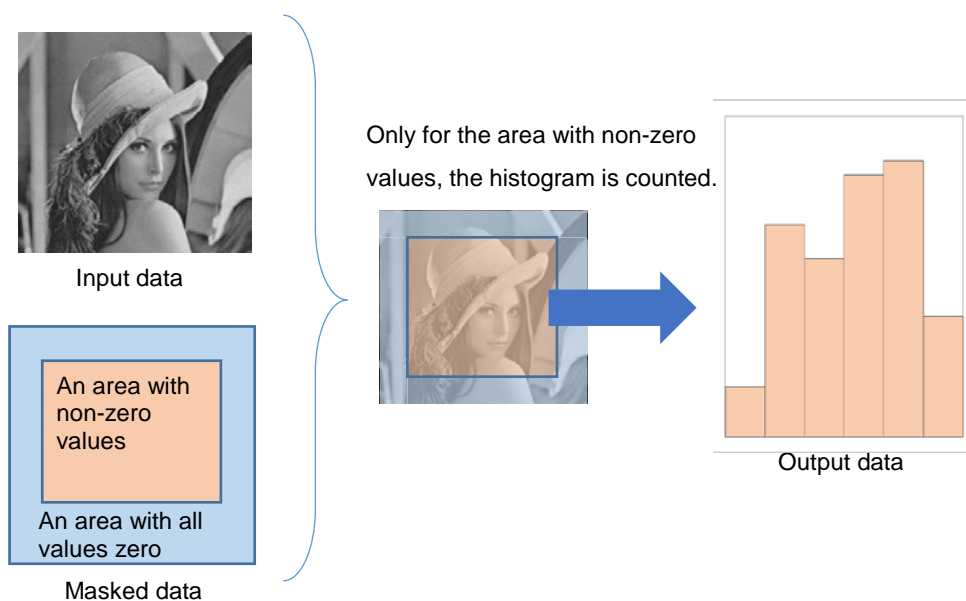

The upper limit for the i-th bin becomes  $\text{range} + (i + 1) \times 2$ .

An example of specifying (i + 1) bins is shown below. In the example, for the i-th bin, i is set as the lower limit, and 255 is specified as the upper limit.

This function enables masking of the values for counting to obtain the histogram by using mask.

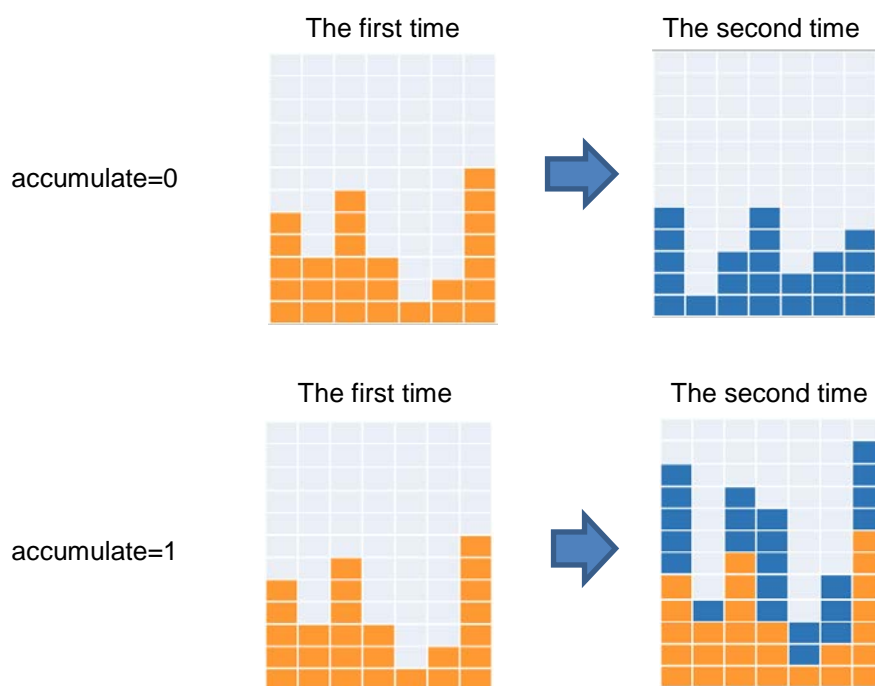

Pixels in areas for which 0 is specified the value are not counted in the histogram, and only values from areas having values other than 0 are counted in the histogram.

This function enables selection of the initial value or accumulated values of the histogram by using the variable `accumulate`.

Specifying `accumulate` as 1 causes reading of the existing results for a histogram at the address specified by `dst`, and the values thus obtained are set as the initial values. Specifying `accumulate` as 0 causes all of the initial values of the histogram to be set to 0.

Therefore, if accumulation is to be performed, the bin specifications (`hist_size` and `ranges`) cannot be changed from histogram to histogram. If the frequency exceeds 4,294,967,295 ( $= 2^{32} - 1$ ), the value is limited to 4,294,967,295.

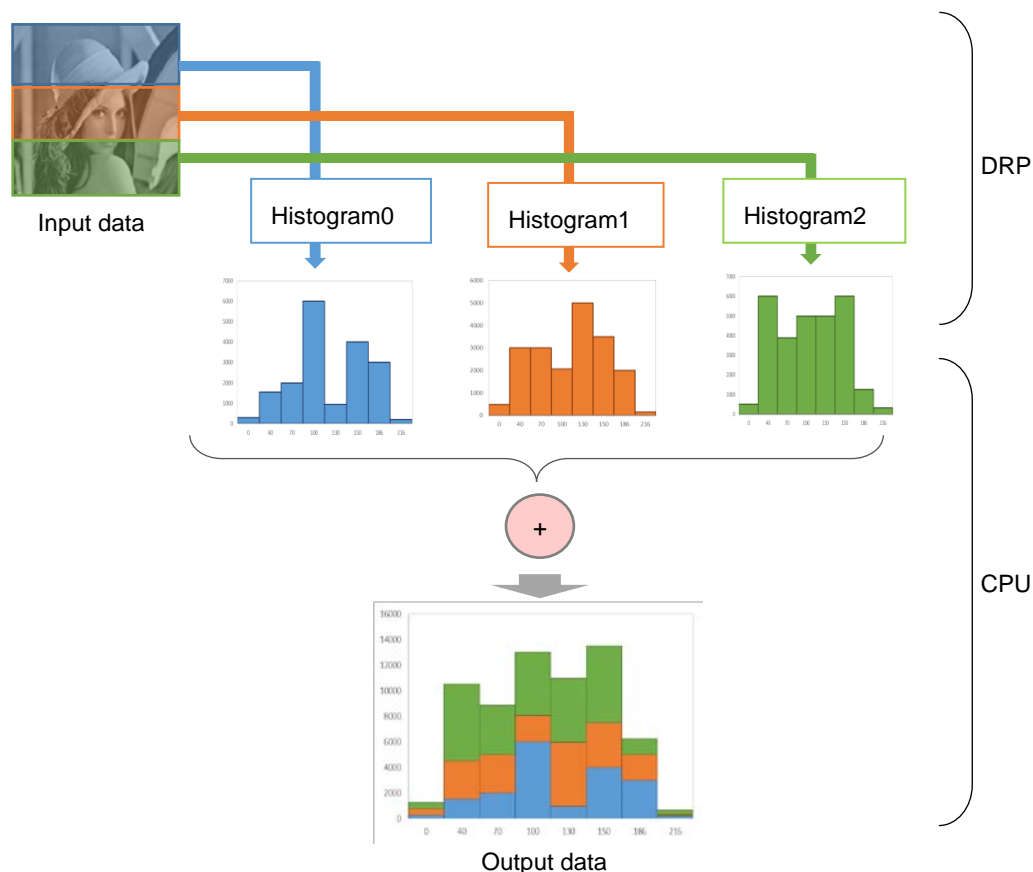

This function allows segmented processing with the aid of the CPU.

An example of three parallel flows of processing with the setting `accumulate=0` is shown below.

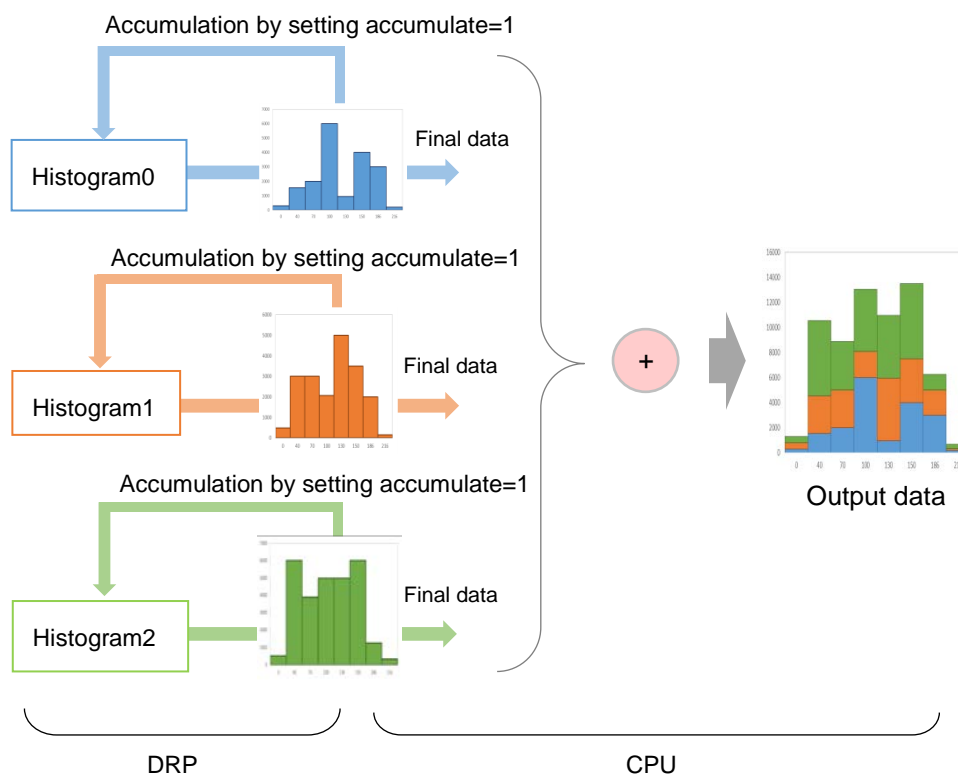

The input data are segmented into three areas: Histogram0, Histogram1, and Histogram2. The prescribed `dsrc`, `dst`, and `mask`, (and `data_size` as required) are specified for the respective areas. The parameters ranges and `hist_size` are to be the same.

The segmented processing is enabled by the CPU obtaining the total of the frequencies in corresponding bins in the `dst` areas for Histogram0, Histogram1, and Histogram2 after the DRP has calculated the histograms.

An example of three parallel flows of processing with the setting `accumulate=1` is shown below.

If 1 is set for `accumulate`, segmented processing is enabled by adding up the frequencies of each bin in the `dst` area by CPU after the completion of accumulation in response to this setting of `accumulate`.

The processing performed by this function is equivalent to that of the OpenCV `cv::calcHist` function with specifying 1 to `narrays` argument, {0} to `channels`, 1 to `dims`, and false to `uniform`.

Note

None

## 5. Using the DRP Library

To use this library, it is necessary to initialize the DRP, load configuration data, etc. Also, since the parameters are different for each configuration data, set the parameters based on the specification of the configuration data to be used. For application example of DRP library, refer to "RZ/A2M Group 2D Barcode Application Note (R01AN4503)".
